Documentation for the Electricity Access & Poverty Energy

Step 1:

I gathered my correct files which allowed me to see the relevant data which compromised of the data sources and their last update checkpoints this information revealed the country name columns along with the merged column of which then compromises of the country code and it is under the date of the current year which or indicates the last check point of 2026-07-13. The other columns following represent the indicator name and the indicator code and the following subsequent columns represent the years which dates back from 1960 till the current year of 2026.

The actual data did entail a few blank spaces across the sheet is as of a result of the two columns for year 1960 and the year 1989 were almost nearly empty for every country, this is due to the fact that (data collection for this indicator only really starts around 1990, and doesn't hit full coverage until 2010).

So to clean up the data I picked up one reporting year (2023) whereby an aggregated calculation of the popular formulas for the population sheet and connected it back to the electricity sheet where I calculated a vlookup on the column's data to this then

resulted into a new column creation for the Electricity sheet of the Access Cell Rate for that year.

This result of the new column creation was part of the beginning cleaning stages

Step 2:

- Sorted the data by column I (Population Rank), This puts the countries with the most people lacking electricity at the very top.
- Filtered for the top 10 rows and managed to filter down with Access Rank and Population Rank for each.

Step 3:

Highlighted the 3–5 largest unserved populations
